ABSTRACT

Agriculture plays a central role within the Ethiopian economy. In our country, concerning 85% of total population depends on agriculture and its product. This implies agriculture provides a good portion of national product growth. In spite of the importance of this sector, production and productivity area units restricted by varied biophysical, social and economic aspects. Soil fertility decline is one of the central issues that scale back Ethiopian agriculture and at last, it ends up in poverty and starvation. The main causes of those entrenched challenges are the land degradation showed in type of soil fertility decline, as introduced by varied hindrances as deforestation, overgrazing and through a consequence of wearing away, deposit, pollution, etc. Hence, the core objectives of this review are to evaluate the soil fertility status in Ethiopia, the sources of soil fertility decline and find improved resolutions to soil fertility in Ethiopia. As the physiological factors of the country are rugged with dynamical sorts of soils, preponderantly the upland wherever regarding 90% of the tillable land is concentrated, difficulties such as soil erosion, meager and incessant cultivation are the chief reasons of soil fertility loss. Thus, the application of combined soil fertility management approach with presence and mixture of manure, compost, crop rotation, soil protection practices provides improved production and saves the soil fertility standing to an improved level. The apply undertaken by the government of Ethiopia, is that the application of optimum rate of...
fertilizers, but it's not thriving as a results of various factors like amendment of agroecology, edaphic factors, the social and economic state of affairs of the farmer, repair to property combined soil fertility management to get high yield while not compromising the soil fertility position within the future, this can be broad and needed to be followed.

Keywords: Soil fertility; causes of soil fertility; integrated nutrient management practices; and crop production.

1. INTRODUCTION

Ethiopia shares the broad characteristics of agriculture in the Sub Saharan African. Agriculture is the most important sector in Ethiopia, and it is the mainstay of the Ethiopian economy. It accounting for 46% of its gross domestic product and 90% of its export earnings [1,2,3]. However, in general, the main issue in Sub Saharan African agriculture, particularly in Ethiopia, is soil fertility decline. In Ethiopia, the population is hardly glad by reliable production, instead, a decline in their crop yield is holding them suffer from the economic condition and deficiency disease [4,5]. Studies indicated that in some elements of Ethiopia farmers suffer from lack of what to eat notably in months ranging from June up to Sep [6,4,5]. Farmers in most elements of the country work flat out, in seasons of the year once the rain is favourable for his or her cropping; despite their effort [4,5]. They obtained little, which does not aid them to escape their existing system of living.

The problem connected with agriculture is extremely convoluted in nature, the complexness arises from numerous condition of the country like the agro-climate, topography of the lands, the soil varieties and socio-economic standing of the farming community and therefore the combination of these; the general result of that is finally mirrored by soil fertility decline and reduction in yield of crops [4,5]. In the growth method of agriculture, farmers disafforest the present forest lands and convey a brand-new kind of land use and on their agricultural land, they nearly take no organic matter management [4,5]. Besides, eutherian productions on unprotected land cause overgrazing method and blank the land of grasses, which directs the land to be susceptible to additional degradation through erosion [4]. Of these issues influence a loss in soil fertility of the country; on the average Ethiopia losses concerning 42 t/ha/year soil [7,4,5]. With this quantity of soil, the number of plant nutrients like organic matter applied fertilizers are removed through erosion; these build the soil tough to character and at last, decrease the productivity of the soil [7]. This decline of soil fertility is seriously littered with incessant cultivation, which results in nutrient removal of the soils.

Even if the farmers of the country have autochthonous data in what due to manage their ranches, however, the resource they possess limit them to not do the managements practices like organic matter by deed the crop residue on the sector and additionally to use the trash or manure to their field [8,4,5]. There are a variety of researches done by completely different stakeholders to deal with the issues of soil fertility, however, most of those targets the appliance of various forms of inorganic fertilizers and therefore the use pesticides for the resource-poor farmer is nice challenges to pay it for them [4].

Irrespective of the various native analysis studies in Ethiopia as yet the fertilizer application is undertaken by farmers is predicated on a national level forwarded by the government [4,5]. It's supported some general soil studies, for immediate resolution of production issues of the country; and this national fertilizer recommendation is understood because the blanket recommendation, however, it's currently found to be associate in nursing old follow that can't address the prevailing condition of the farmers [4,5]. If scholars ought to do a quest to deal with the issues of the farming community, it ought to be in collaboration/participation with the farmer himself, within the manner that he/she is in a position to research the matter and perceive the solutions given on his farm by deciphering to his own normal [4].

It is investigated that the farmer’s practices and perceptions/knowledge’s are terribly valuable, as an example, farmers completed in some components of Ethiopia that the fertilizer application to relinquish a more robust yield for cereal cultivation the cereal ought to follow a rotation of some quite legume crop and this can be found to be authentic crops like teff and wheat [4,5]. Consequently, collaborating the assorted farming schemes and agronomical activities will support to deal with the challenges of soil fertility
2. THE SOIL FERTILITY STATUS IN ETHIOPIA

In the totally different regions of Ethiopia, there exist numerous geographies, environmental conditions or agro-climatic and soil conditions [4,5]. These varied conditions at the side of the socio-economic standing form various factors that influence soil fertility decline with totally different degrees. So, the soil fertility standing of the country cannot simply be generalized, for the explanation that there are numerous native soil fertility statuses which will vary from fertile soil to unfertilized soil [9,4]. But generally, the soils of most square measure a geographic area significantly the geographical region soil are generalized as barren with “Orthodoxy” [4,5]. Orthodoxy is to mean that physiological condition of the soil during this region is a comprehensible development, that doesn't would like proof [10,5]. Or within the original spoken language “the existence, the extent and causes of soil fertility drawback area unit accepted while not question” [10,4].

The fertility of the soil and its productivity is larger than simply plant nutrients and might be outlined because of the physical, biological, and chemical characteristics of soil, for instance, its organic matter content. In line with this, Belay [4] reported that acidity, texture, depth, and water-retention capability all influence fertility [11,9,5]. Since these characteristics varied between soils, soils dissent in their quality. Similarly, Belay [4] reported that some soils, owing to their texture or depth, for instance, area unit inherently productive as a result of they will store and build obtainable massive amounts of water and nutrients to plants [11,5]. Similarly, alternative soils have such disadvantaged nutrient and organic substances that they are virtually sterilized.

Even if the soil fertility standing of Ethiopia isn't documented well, its low fertility standing is exhibited, by a number of the macronutrient, and organic matter, CEC (Cation Exchange Capacity) and; pH levels of the various areas [4,5]. As already explicit earlier the soil fertility standing in Ethiopia numerous among the various condition, for instance, the variation within the agro-ecological zones and variations inside plots during a farm is indicated in Table 1 [12,4]. Fertility standing of the soil can also take issue among comparison fields that area unit within the similar soil sorts, as an example, soils around the homestead area unit comparatively fertile, in comparison with soils that area unit remote from homestead (outfields) [13,4].

To strengthen the on prime of clarification, we have a tendency to are able to take a study created at Ethiopian highlands, which indicates that there is variation in fertility standing of soils between homestead and piece of ground areas in Enset (Ensete ventricosom) growing [4]. The result suggests that the variation in soil fertility is not alone due to nutrient deficiency (unavailability), but it's likewise due to the existence or absence of soil organic matter [14] (Table 2).

In the four-year study (2001-2004) on Enset (Ensete ventricosom) on farmers field, farmers square measure classified as resource-rich (G1) and resource-poor (G3), supported their capability of allocation of resources to their agricultural enterprise, there's associate degree discovered variation in soils among teams and sort of farms [15]. Within the study, the yield elements and nutrient contents of the Enset are compared for the homestead and tract plantation [4,15]. Hence, in line with Belay [4] it's found that the homestead soil has higher contents of macronutrients like N, P, K and Ca, however, the Enset plant took up 150% larger amounts of the macronutrients for the outfields than the homestead [4,15]. However, the yield attributes of the Enset reduced by 90% for height and reduced by 50% for pseudo-stem diameter in tract farm relative to the homestead [14,15].

The decline within the yield attributes could be a reflection of the fewer amounts of organic matter within the parcel of land, that resulted in tide
holding and retention capability of the soil, with the consequence of decline within the yield components of Enset due to wetness stress, instead of nutrient stress [14,15]. No matter it’s, the parcel of land soils are impotent or has lost its fertility in terms of its organic matter content [4]. Though the Enset plant absorbed roughly adequate amounts of the nutrient, however, there occurred a yield decline as discovered on its yield elements [15]. Here we will see that the fertility standing of the soil within the farmers' own field is lower due to less organic matter content of soil, which resulted in wetness stress of the soils [14,4].

The spreading downside in Ethiopia, an investigation created by brandy (2007) as cited by Zelleke et al. [16] indicates that soils of the various areas are often rated as low regarding their organic matter and total element content [4,5] (Table 3). For soil to be productive, it has to have an organic carbon content in the vary of one. 8-3.0% to attain an honest soil structural condition and structural stability [4,17,5]. Within the same document, it’s tabulated that soil with organic carbon of 1% chronicles and fewer are taken into account as low to extraordinarily low [4]. The element rating of soil is additionally indicated as high once its soil concentration is within the vary of 0.25-0.5%, however, are often thought- about as low below these values [18,3,4]. Therefore, we will see that each share of organic carbon and element in low in most areas of Ethiopia.

On the opposite hand, a study created in Southeast Ethiopia, on soil fertility standing supported farmers' fertility naming indicates that soil samples taken at totally different depths and analyzed victimization normal laboratory procedures have shown the distinction in fertility standing [4,5]. Farmers’ fertility naming goes in conformity with the laboratory analysis, notwithstanding farmers use qualitative strategies to category the fertility standing of the soils [10,4]. The clay content of the soil will increase down the depth, but the pH, organic matter content, and total N decrease down the soil depth [5]. However, on rating the soil fertility standing supported the laboratory analysis victimization parameters like organic carbon, CEC, pH scale, and a few nutrients, is ascertained that, the soil of the southeast is low to medium in its organic carbon content, low to medium in total N, lower to medium in CEC and adequate in pH scale [10,4]. Therefore, per the on top of observation, it is completed and generalized that there's low soil fertility standing in southeast Ethiopia.

3. THE MAJOR EXPLANATION FOR SOIL FERTILITY LOSS IN ETHIOPIA

A few decades ago, most soils of Ethiopia were coated by vegetation and therefore the fertility of the soil was more contented, for instance within the 1960-1970s [4,5]. However, with associate degree increasing population, the pressure on lands escalated, through deforestation, overgrazing and continuous cropping with this method out of print [4,5]. Thus, most soils lost their fertility, in terms of the property, and chemical properties, like macronutrient, matter and organic matter depletion [18,4,5].

For all the fertility losses their area unit varied causes within the totally different regions of the country, in totality, the most reason of soil fertility reduction is land degradation, that is full of the various agents like eroding, deforestation, overgrazing, deposit, continuous farming, and pollution [4,5]. The main causes of eroding and deposit don't seem to be solely high intensities of downfall and floods; however, the matter is far aggravated by deforestation and overgrazing, within the absence of the two, eroding and deposit can stay to the minimum [6,4,5].

According to Abera [6] has been explained the main cause for soil fertility decline except for convenience of this review we have a tendency to focused on two issues: the wearing and continuous cultivation as major causes of soil fertility decline; as a result of the opposite causes area unit the contributors for the two major causes [4,5]. In most components of continent notably geographical region, the main causes of soil fertility decline area unit wearing, poor organic matter management, continuous cultivation, etc. Within the study created in Kenya, the causes of soil fertility decline area unit given completely different scores and so hierarchic to screen the main cause and it's found that erosion is that the first major reason for the matter [19,5,4].

4. SOIL EROSION

Wearing is represented because of the method of loss of nutrient-rich clay and organic matter as a result of the driblet splash, impoverishing the higher soil, whereas resulting erosion peels off the higher soil layers [20,4,5]. In Ethiopia due to
the surface geographic condition of most cultivable lands that concentrate within the highland, the matter of wearing may be a serious one [4]. During this condition Ethiopia losses of soil area unit concerning 137 t/ha/year, once this quantity of soil is calculable in terms of soil depth it is concerning 10 mm [4]. Correspondingly, Belay [4] according that the speed of soil loss is incredibly high in Ethiopia compared to the speed of soil formation, below agricultural condition, in general, the soil loss is concerning ten mm/ha/year, and formation of this depth of soils takes place in concerning two hundred years [21,5].

Vegetation cowl determines the extent of eating away in Ethiopia, attributable to the rugged topography of Ethiopia, therefore agricultural fields square measure most liable to erosion effects as they are practiced on sloping lands [4]. Moreover, underneath semi-arid conditions, there are commonly distributed ground cowl at the onset of rains, resulting in comparatively severe rates of runoff and soil loss [22,4,5]. Underneath the Ethiopian condition, we measure able to see that croplands are a lot of at risk of erosion and soil loss (Table 3) [4,5].

When the surface soil is removed by erosion, the clay content of the remaining soil will increase, however, the organic matter content decreases, that is a sign of unfavourable conditions and loss of soil fertility [5,4]. The study created at completely different times on Vertisols of Ethiopia indicates the loss of surface soil ends up in high clay content, as a result of soil depth will increase the clay content of the Vertisols soil increase [23,5]. The reduction of topmost soil ends up in decrease of assorted soil nutrients, as an example, the N, with a significance of yield reduction. A study in South and East Ethiopia on two cereal crop maize and wheat indicated that there's loss of crop yield for these crops because of loss of N from the soil within the Table 4 [24,5].

5. THE REMEDIAL ANSWER IS GIVEN TO RECOVER SOIL FERTILITY

As an answer to soil fertility drawback the Ethiopian government, in a very expected value, have forwarded fertilizer recommendation for the two major macronutrients element and phosphorus, at a rate of one hundred and fifty kg/ha within the type of organic compound and DAP (di ammonia phosphate), severally [27,4]. However, this recommendation is unable to unravel the matter evidently as a result of the soil below every agro-ecologic condition is variable or maybe the soil conditions in a very single farm are variable, therefore managing such condition below the blanket recommendation isn't valuable [4,5]. In particular, the farmer cannot afford this blankets recommendation thence regarding 87% of farmers apply lesser fertilizer rate of 50 kg/ha organic compound completely, departure the DAP [27,4]. The government is making an associate in nursing energy to own agroecology-based recommendations of fertilizer for the areas of main nutrients limiting crop production.

There are several efforts within the type of researches and numerous comes to enhance the keep of the farmer farming community to reverse the fertility of the soil and increase productivity per unit land [4,5]. Belay [4] accomplished and over that this can be being undertaken by governmental and non-governmental organizations; here we wish to comment that the results from the simplest researches and comes ought to be enclosed within the agriculture policy of the country to come back to affect [5].

6. THE ROLE OF INTEGRATED SOIL FERTILITY MANAGEMENT

Integrated soil fertility management refers to a group of soil fertility management practices that essentially embrace the employment of fertilizer, organic inputs, and improved crop varieties combined with the information on a way to adapt these practices to native conditions [4,5]. Aiming at maximizing agronomical, the employment potency of the applied nutrients and up crop productivity.

That is as a result of the revolution thought by the government of Ethiopia incurs the farmer into high prices of fertilizers and pesticides, though a credit facility is provided to the farmer, he/she cannot afford the price because the yield obtained is not equalization it well [4,5]. What is
more, the advice reportable by the government doesn't take into account the native condition of farmers. Hence the principle of revolution in Ethiopia underneath the blanket recommendation isn't made underneath most conditions [4,5].

Then, additional analysis's got to be done underneath farmers condition together with his own participation in such a fashion that the research is in a position to reduce the various styles of native issues, by reducing the soil fertility loss and decline in productivity, underneath what's referred to as the integrated soil fertility management [27,4,5].

7. THE MAIN GOAL OF INTEGRATED NUTRIENT MANAGEMENT

Sustainable agricultural production incorporates the concept that natural resources ought to be accustomed to generate redoubled output and incomes, particularly for low-income teams, while not depleting the resource base [28,4]. During this context, it maintains soils as storehouses of plant parts that area unit essential for vegetative growth. Its goal is to integrate the employment of all-natural and synthetic sources of plant nutrients, so that crop productivity will increase in associate degree economical and environmentally benign manner, while not sacrificing soil productivity of future generations [5]. It depends on a variety of things, as well as acceptable nutrient application and conservation and also the transfer of data concerning its practices to farmers and researchers.

8. APPLICATION WAYS THAT OF INTEGRATED NUTRIENT MANAGEMENT

Integrated Nutrient Management ought to be applied in a manner that everyone kind of soil fertility losses area unit reduced, like eroding, and nutrient mining from the soil and causes that lead to these two major issues. IFDC (International Fertilizer Development Center)-Africa promotes ISFM (Integrated Soil Fertility Management) through a democratic and process-oriented approach that builds on a solid understanding of native settings, autochthonic data, and scientific experience, and targets at totally different abstraction and temporal scales each technological and institutional amendment [5,4]. The quality of farmer reality needs a lot of stress on farmer experimentation and democratic learning, and building of partnerships between soil fertility management stakeholders (farmers, credit suppliers, input dealers, analysis and extension agencies, government) from village to the district to national level [29,4,5].

In an analysis done at Gonuno, in Wolayita, in democratic approach with farmers it's known that the subsequent steps as a part of integrated nutrient management will be applied to stay the soil fertile and productive [30,4,5]; i) implement physical and biological measures to reduce soil loss caused by water erosion; ii) analysis of the soil to spot the limiting soil-related issue (nutrients, hydrogen ion concentration and alike); iii) increase soil organic matter content by incorporating crop residues and manure into the soil and growing legume cowl crops; iv) improve the water-holding capability of the soil by contour tilling, minimum tillage and adding organic matter, and v) increase soil nutrient levels with applications of mineral and organic fertilizers [3,5], and by growing N-fixing legumes and vi) use crop rotation, intercropping and relay cropping schemes to reduce losses and enhance fertility, with mixtures of deep and shallow stock-still crops, and by growing soil-enriching species with people who eat up the soil [4,5].

9. IMPROVEMENTS IN YIELD OF CROPS THROUGH INTEGRATED SOIL FERTILITY MANAGEMENT

Many kinds of research have shown that neither inorganic fertilizers nor organic sources alone may result in property productivity [31,32,5]. Moreover, the worth of inorganic fertilizers is increasing and turning into too high-priced for resource-poor smallholder farmers. Consequently, Geremew [3] realized and finished that the simplest remedy for soil fertility management is, a mixture of each inorganic and organic fertilizers, wherever the inorganic fertilizer provides nutrients and also the fertilizer, mainly, will increase organic matter and improves soil structure and buffering capability [33,32,3]. The combined application of inorganic and organic fertilizers sometimes termed integrated nutrient management, is widely known as how of skyrocketing yield and/or up the productivity of the soil sustainably [34,3].

In highland elements of Ethiopia, the employment of integrated soil fertility management offers high yields compared with ancient cultivation [5,4]. For example, in Benishangul Gumuz region analysis done on woredas, Agalometi and Sirba indicate that a mixture of few scientific discipline management practices like tillage (not native type), application
of manure and compost resulted in higher yields of various kinds of maize [35,4,5].

In the study tilling alone (P< 0.05) improved the common maize yield in 2002 from 7.9 to 9.5 t/ha [4,5]. Correspondingly, tilling and adding either manure or compost additionally resulted in higher yield in 2002 (10.1 and 10.0 t/ha, P<0.05) [4,5]. However, there was no distinction between the 3 best treatments [34,4]. Belay [4] reported that in Nitisols, of South Ethiopia, a study indicated that victimization tree *brui*ce as a manure crop either its biomass alone or together with mineral fertilizer is found to extend the yield and yield elements of bread wheat [36,4,5]. Within the same approach, Belay [4] represented that *E. bruice* may be a nitrogen-fixing plant; this tree is endemic to Ethiopia, and may be an aggressive and nutrient-rich plant significantly high with nutrient contents because of the NPK [36,5].

Combined information analysis of the 2 seasons discovered that there was a distinction among treatments in their result on grain yield of maize [36,4,5]. Within the same approach, Geremew [3] reported that the appliance of five and ten t/ha of *E. bruice* biomass hyperbolic the grain yield of wheat by 82% and 127% over the management, severally [4]. Similarly, the appliance of the counselled dose of NP fertilizer has hyperbolic the grain yield by one hundred forty-five over the management [5,4]. Yet, the best grain yield was obtained from plots that received a combined application of *E. bruice* biomass + inorganic fertilizer applied [4]. These treatments hyperbolic the grain yield of wheat by 173, 190 and 227% over the management, severally [36,4].

It is a widely known incontrovertible fact that the use of manure will increase the yield of crops, although it's not sensible by most farmers [36,4,5]. Geremew [3] reported that, regardless being an aggressive tree reaching up to six m height at intervals three months, *E. bruice* contains an important agroforestry attributes like, spreading leaves, supply of enormous quantities of fleetly analyzable litters, vigorous re-growth, copious coppering in addition as speedy recovery once a spell of prolonged drought [37,38,4,5].

In Western elements of Ethiopia, particularly in Hararghe, the decline in soil fertility is additionally investigated that the most downside for the decline in crop productivity due to lack of farmyard manure [39,4,5]. Geremew [3] reported that since to recover the soil to its productive state it's not enough to use mineral fertilizer alone, therefore, integrated nutrient management is that the best life for increasing crop production. supported these factors, a study was realized and finished that, a combination of four t/ha FYM +75 metric weight unit N/ha with sixty metric weight unit P/ha performed best among others, with maize yield of eight [5,4]. It's indicated additionally that the appliance of ten t/ha FYM alone will offer as equal yield as a hundred and a hundred metric weight unit P/ha along [39,5,4]. Within the space there area unit variety of districts like Chiro, Doba, Tullo, Mesela, Gemechis, Kuni, Boke Habro and Daro Labu, wherever soil productivity is severely affected by poor soil fertility and poor crop management practices [5,4]. It was determined that, during this case, the yield is little, sometimes but a pair of t/ha as compared to a possible yield of over five tons/ha within the region [40,5,4].

A combination of organic and inorganic fertilizer is vital to extend the soil fertility, however conjointly the apply of minimum/zero tillage and residue management together with mineral fertilizer application [4,5]. In a very 5 years study (2000-2004) in western Ethiopia, the employment of zero tillage with residue retention on the sector was higher than the zero tillage and therefore the standard tillage [41,5,4]. Within the study, 3 N fertilizer rates were applied together with the tillage systems [4]. The principal rate of N fertilizer was 92 kg N/ha and therefore the different two rates were twenty-fifth bigger than and twenty-fifth but the principal rate [4,5]. When two years, was discovered a higher yield of maize in zero tillage and standard tillage [41,5,4]. The study reflects that the combination of minimum/zero tillage and residue management, with mineral fertilizer, offers a bonus over the traditional fertilizer application [5,4].

In some semi-arid regions of Ethiopia wherever there's a shortage of soil wetness due to shortage of rain, the employment of tie-riding at the sowing amount and application of mineral fertilizer magnified the yield sorghum [5,4]. Geremew [3] complete associate degree experiment with completely different tillage practices and fertilizer applications. The result then indicated that tie-riding together with fertilizer application was the simplest apply, higher than the opposite tillage apply even with fertilizer applications [4,5].

As reported by Belay [4], the experiment conducted 2 years (2002-2003) on two native sorghum varieties Woitozira and Chibal (*Sorghum colored* L. Moench) showed a rise in
yield in vary of 7-48% for tie-ridging at planting with fertilizer application relative to the opposite treatments [41,3,4]. The most reason here was wetness conservation capability of the tillage apply was a lot of advantageous than tie-ridging when four weak and ridging while not tie creating [4,5].

10. CONCLUSION

In Ethiopia, the most causes that decline within the fertility of soil are wearing, continuous cultivation, and low nutrient application. In a very case, the depletion of each soil organic matter and loss of superficial soil worsens the issues of soil water-holding capability. This is often important in soil huminless stress and nutrient shortage. Thus, the observe of mistreatment of advice rate of mineral plant food in addition to alternative chemicals like pesticide, pesticide, herbicide, etc. Application solely in Ethiopia doesn't seem to be a satisfactory resolution to the current downside within the side of the agriculturalist. Therefore, the chief resolution ought to be considering the multifarious interactions of agro-climate, soil, geography and therefore the condition of the neighborhood.

Integrated soil fertility management is that the core choice to resolve the occurred soil nutrient downside in Ethiopia. It's important to look at the enchaigned interactions and varied effects of the agroecology, edaphic factors, and therefore the setting with the various agronomical activities. Once the enchaigned interactions and its effects are clear renowned, it'll be wise to supplement and suggest totally different field operations and important inputs that are effective to the farmers. As per the understanding of various interactions of agro-ecology, and extra technologies play a key role in enhancing the effectiveness of the agronomical observe and finally up the assembly and productivity of the crop. Moreover, agronomists that shall do analysis ought to concentrate on the participatory analysis methodology field, which is additionally important to resolve the various downside that faces our country. This includes soil management practices like conservation tillage, totally different cropping systems, and organic matter application has to be applied in conjunction with a combination of alternative varied property systems. Therefore, it's higher to use of integrated soil fertility management instead of employing a single nutrient, as a result of it's the plays an excellent role in up the assembly and productivity of crops.

11. RECOMMENDATION

Ethiopia could be a tropical country that features a multi agro-ecological zone and landforms. It's economy and food security rely, mainly, on agriculture and agricultural merchandise. In several regions of Ethiopia, there are various land features, agro-climatic and edaphic factors, and these totally different things in conjunction with social and economic standing form totally different causes for soil fertility decline with different degrees. This loss of soil fertility is any aggravated by continuous cultivation, which results in nutrient mining of the soils.

As the increase in the population of the country, the various farming systems practiced by the farmers like falling and shifting cultivation are discontinued. This creates a series downside to individuals feed an outsized family unendingly. So, for future times governments ought to tend attention to the adoption of farmers settle for new technology on soil management follow. In general, cultural sectors, researchers, governments and students ought to have responsibility to manage soil fertility and scale back its losses by giving awareness to farmers to used integrated soil fertility management and adoption of recent returning technology.
